1 Introduction

This document provides a working definition of what is the architectural stance and the design decisions that shall be adopted for the eProcurement ontology along with the description of how to generate it.

1.1 Background considerations

Public procurement is undergoing a digital transformation. The EU supports the process of rethinking public procurement process with digital technologies in mind. This goes beyond simply moving to electronic tools; it rethinks various pre-award and post-award phases. The aim is to make them simpler for businesses to participate in and for the public sector to manage. It also allows for the integration of data-based approaches at various stages of the procurement process.

Digital procurement is deeply linked to eGovernment. It is one of the key drivers toward the implementation of the “once-only principle” in public administrations – a cornerstone of the EU’s Digital Single Market strategy. In the age of big data, digital procurement is also crucial in enabling governments to make data-driven decisions about public spending.

With digital tools, public spending should become more transparent, evidence-oriented, optimised, streamlined and integrated with market conditions. This puts eProcurement at the heart of other changes introduced to public procurement in new EU directives.

PSI directive [20] across the EU is calling for open, unobstructed access to public data in order to improve transparency and to boost innovation via the reuse of public data. Procurement data has been identified as data with a high-reuse potential [3]. Therefore, making this data available in machine-readable formats, following the data as a service paradigm, is required in order to maximise its reuse.

Given the increasing importance of data standards for eProcurement, a number of initiatives driven by the public sector, the industry and academia have been kick started in the recent years. Some have grown organically, while others are the result of standardisation work. The vocabularies and the semantics that they are introducing, the phases of public procurement that they are covering, and the technologies that they are using all differ. These differences hamper data interoperability and thus its reuse by them or by the wider public. This creates the need for a common

data standard for publishing public procurement data, hence allowing data from different sources to be easily accessed and linked, and consequently reused.

In this context, the Publications Office of the European Union aims to develop an eProcurement ontology.

The objective of the eProcurement ontology is to act as this common standard on the conceptual level, based on consensus of the main stakeholders and designed to encompass the major requirements of the eProcurement process in conformance with the Directives and Regulations [21, 22, 23, 24].

1.2 Target audience

The target audience of the eProcurement ontology, defined in [33], comprises the following groups of stakeholders:

- Contracting authorities and entities, i.e. buyers, such as public administrations in the EU Member States or EU institutions;
- Economic operators, i.e. suppliers of goods and services such as businesses, entrepreneurs and financial institutions;
- Academia and researchers;
- Media and journalists;
- Auditors and regulators;
- Members of parliaments at regional, national and EU level;
- Standardisation organisations;
- NGOs; and
- Citizens [33].

1.3 Context and scope

In the past years much effort was invested into the eProcurement ontology initiative, including definition of requirements, provision of general specifications, identification of the main use cases, and laborious development of a preliminary shared conceptual model expressed using Unified Modelling Language (UML) [7, 10].

The general methodology for developing the eProcurement ontology is described in [19, 3–15]. It describes a process comprising the following steps:

1. Define use cases
2. Define the requirements for the use cases
3. Develop a conceptual data model
4. Consider reusing existing ontologies
5. Define and implement an OWL ontology

The ultimate objective of the eProcurement ontology project is to put forth a commonly agreed OWL ontology that will conceptualise, formally encode and make available in an open, structured and machine-readable format data about public procurement, covering end-to-end procurement, i.e. from notification, through tendering to awarding, ordering, invoicing and payment [33].

Work so far has concentrated on the conceptual modelling of the eNotification phase, taking into consideration the needs of other phases. The UML conceptual model has been created with the forthcoming procurement standard forms (eForms) in mind; the model has not been mapped to the current standard forms.

In the 2020 ISA² work programme a new project has been set up to analyse existing procurement data through the lens of the newly developed conceptual model. This means that the conceptual model needs to be transposed into a formal ontology and a subset of the existing eProcurement data (initially only the notification phase is considered) must be transformed into RDF format such that they instantiate the eProcurement ontology and are conform to a set of predefined data shapes.

Working under the assumption that Steps 1–4 have been completed, the current efforts channel on designing, implementing and executing the necessary tasks in order to accomplish Step 5 from the above process.

Once the formal ontology is created and the XML data is transformed into RDF representation, the data can be queried in order to validate the suitability to satisfy the business use cases defined in [19, Sec. 3].

This document comprises of architectural specification and implementation guidelines that shall be taken into consideration when developing the formal ontology. Other related artefacts (i.e. documents, scripts and datasets) are presented in Sec-

tion 3, where is described, in detail, the process for accomplishing the generation the formal eProcurement ontology, transformation of XML data and the ontology validation.

There is a number of aspects that are excluded from the scope of this project stage:

- Change management and maintenance of the ontology content.
- Content authoring and conceptual design of the domain model.
- Practical implementation of systems that implement the ontology.

Currently in scope are the following items:

- designing an ontology architecture (this document),
- create guidelines and conventions for the UML conceptual model [11],
- develop a set of transformation scripts from the UML model into a formal ontology
- implement a set of scripts to transform the existing XML eProcurement data into RDF format,
- put forward a method to validate the generated formal ontology using the current eProcurement data.

1.4 Key words for Requirement Statements

The key words “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” in this document are to be interpreted as described in RFC 2119 [8].

The key words “MUST (BUT WE KNOW YOU WON’T)”, “SHOULD CONSIDER”, “REALLY SHOULD NOT”, “OUGHT TO”, “WOULD PROBABLY”, “MAY WISH TO”, “COULD”, “POSSIBLE”, and “MIGHT” in this document are to be interpreted as described in RFC 6919 [43].

2 Requirements

2.1 Functional requirements

This section provides the main functionalities and use cases that the ontology should support. These requirements are derived from the use cases identified in the report on policy support for eProcurement [33] and outlined in the in the eProcurement project chapter proposal [18].

1. *Transparency and monitoring*: to enable verification that public procurement is conducted according to the rules set by the Directives and Regulation [21, 22, 23, 24].
 - (a) Public understandability
 - (b) Data Journalism
 - (c) Monitor the money flow
 - (d) Detect fraud and compliance with procurement criteria
 - (e) Audit procurement process
 - (f) Cross-validate data from different parts of the procurement process
2. *Innovation & value added services*: to allow the emergence of new applications and services on the basis of the availability of procurement data.
 - (a) Automated matchmaking of procured services and products with
 - (b) businesses
 - (c) Automated validation of procurement criteria
 - (d) Alerting services
 - (e) Data analytics on public procurement data
3. *Interconnection of public procurement systems*: to support increased interoperability across procurement systems.
 - (a) Increase cross-domain interoperability among Member States
 - (b) Introduce automated classification systems in public procurement systems

2.2 Non-functional requirements

This section provides the characteristics, qualities and general aspects that the eProcurement ontology should satisfy.

- The practices, technologies and standards must be aligned with the European Directive on open data and the reuse of public sector information [25] and European Publications Office standards and practices.
- The terminology used in the ontology should be reused from established core vocabularies [41] and domain ontologies as long as their meaning fits into the description of the eProcurement domain.
- The concept and relation labels must be multilingual covering at least the official European Languages [40].
- The formal ontology, and the related artefacts, must be generated from the eProcurement UML conceptual model, serving as the single source of truth, through a set of predefined transformation rules [12].
- The content of the ontology must be consistent with the predefined set of UML conceptual model conventions [11].
- The ontology identifiers must follow a strict URI policy defined in Section 6.
- The ontology design must commit long term URI persistence.
- The ontology, and the related artefacts, must be layered in order to support different degrees of ontological commitment and levels formal specification stacked on each other (see Section 4.2).
- The ontology, and the related artefacts, must be sliced in order to support a modular organisation of the domain in terms of self contained or semi-dependent modules (see Section 4.2).

2.3 General design criteria

For the purpose of knowledge sharing and interoperation between programs based on a shared conceptualisation, Gruber [27] proposes a set of preliminary *design criteria* a formal ontology should follow:

- *Clarity.* An ontology should communicate the purpose and meaning of defined

terms. Definitions should be objective and independent of social and computational context even if the underlying motivations arise from them. Formalism is the means to this end, and when possible the logical formulation should be provided.

- *Coherence.* Ontology should permit inferences that are consistent with the definitions. At the least, the defining axioms should be logically consistent. Coherence should also apply to the concepts that are defined informally, such as those described in natural language documentation and examples.
- *Extensibility.* Ontology should be designed to anticipate the uses of the shared vocabulary. It should offer a conceptual foundation for a range of anticipated tasks and the representation should be crafted so that one can extend and specialize the ontology monotonically. This feature supports and encourages reuse and further specialisations of ontologies and creation of the application profiles.
- *Minimal encoding bias.* The conceptualization should be specified at the knowledge level without depending on a particular symbol-level encoding.
- *Minimal ontological commitment.* Ontology should require the minimal ontological commitment sufficient to support the intended knowledge sharing activities. Ontology should make as few claims as possible about the world being modeled, allowing the parties committed to the ontology freedom specialize and instantiate the ontology as needed. An ontological commitment is an agreement to use the shared vocabulary, with which queries and assertions are exchanged between agents, in a coherent and consistent manner. We say that an agent commits to an ontology if its behaviour is consistent with the definitions in the ontology [27].

3 Process and methodology

The main effort of the current stage of the project is to develop a formal ontology. This corresponds to Step 5 of the process described in [19, 3–15] and repeated in Section 1.3.

This section expands and addresses in detail the process of defining and implementing an OWL eProcurement ontology. The underlying assumption is that the

conceptual data model developed at Step 3 serves as an input for the creation of the ontology, and that this process shall be automatic.

In addition to producing the ontology as an artefact, we also need to validate its fitness to represent existing data and test whether the functional and non-functional requirements are respected. Figure 1 depicts the sequence of steps as a BPMN process diagram [46].

Figure 1: The main steps to implementing and validating the formal eProcurement ontology

The conceptual model serves as the single source of truth, the process starts with development of a series of transformations scripts. The conceptual model needs to be adjusted in order to fit a set of UML modelling conventions [11] making it suitable input for the transformation scripts. Provided that the conceptual model is conform, the transformation can be executed. Finally the validation of the formal ontology can be performed using the existing eProcurement data.

The existing eProcurement data needs to be transformed from XML into RDF format. So, in parallel, after the UML transformations are created and along with them, the ontology architecture and UML conventions, then a set of XML transformation scripts can be developed. Once they are ready, they need to be executed on previously selected datasets, to convert them into RDF data instantiating the formal ontology. Only then, when the datasets are available, the ontology can be validated.

The next subsections describe each of these six steps in more detail in order to provide rationale and introduce each artefact in part.

3.1 UML transformation scripts

The process start with authoring two documents laying the foundations of the entire process: the ontology architecture and the UML modelling conventions [11]. The main purpose of the ontology architecture (this document) specifications is to describe why the ontology is being built, what its intended uses are, who the end-users are, and which requirements the ontology should fulfil. Moreover, it states how the ontology should be structured in order to facilitate maintenance and usage patterns.

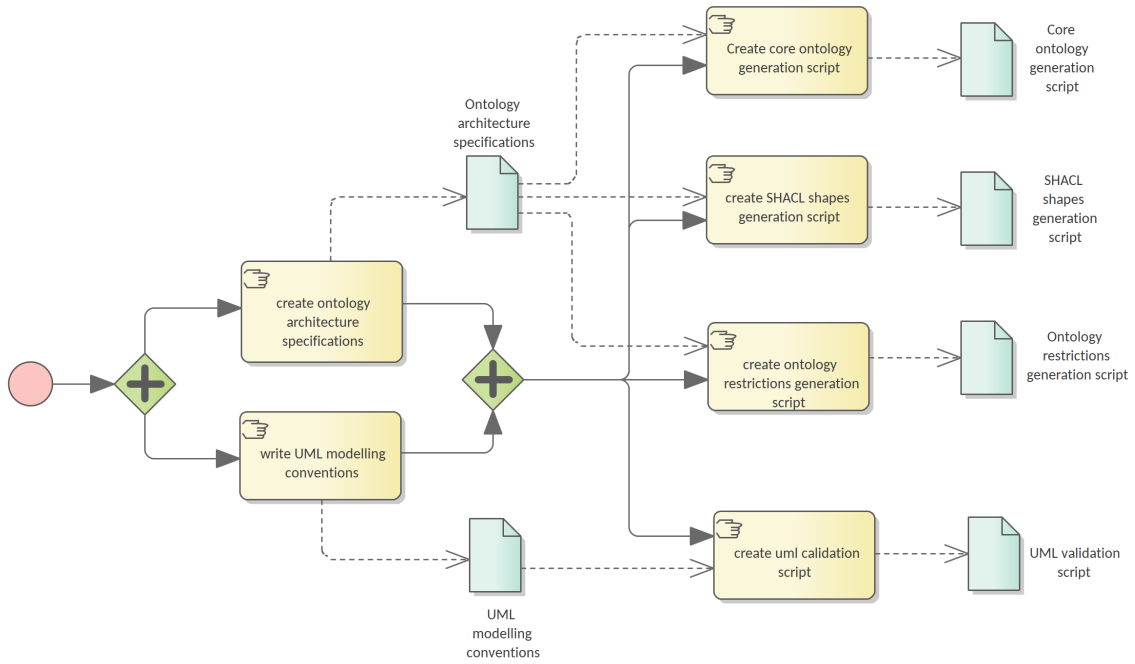

Figure 2: Creation of the specifications documents and the UML transformation scripts

The conceptual model must comply with a set of UML modelling conventions making it suitable input for the transformation scripts, which implement the same conventions. The two parallel actions starting the process are depicted in Figure 2.

The UML conventions document serves, at large, as requirements specification for the XSLT script that checks the UML conceptual model whether it conforms to the conventions.

The ontology architecture specification (this document) serves, at large, as require-

ment specifications for the development of three XSLT scripts to generate the formal ontology. These scripts can be developed independent of each other as they refer to different aspects of the formal ontology as described in Section 4.1.

The input for these scripts is the UML conceptual model serialised in XMI 2.5.1 format [1].

3.2 Conceptual model revision

The conceptual model revision is an iterative process. The validation script is execution outputs a report indicating if there are any deviations from the conventions, and detailing which are they and eventually what are the necessary actions to resolve them.

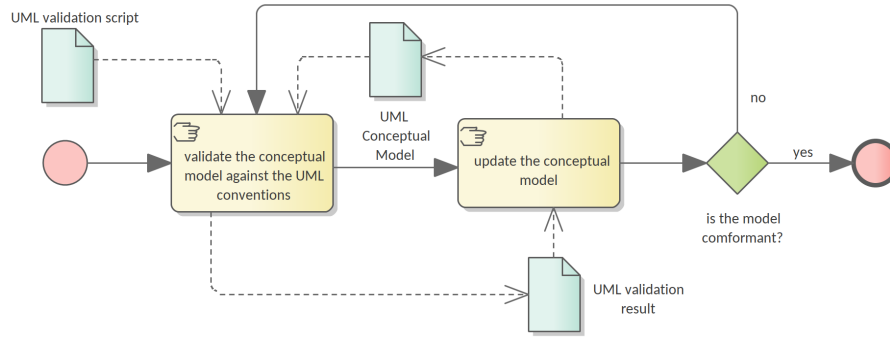

Figure 3: Adjustment of the UML conceptual model guided by the validation script

3.3 Formal ontology generation

3.4 XML to RDF data transformation

4 Architectural considerations

4.1 Separation of concerns

The successful application of an ontology or the development of an ontology-based system depends not just on building a good ontology but also on fitting this into an appropriate development process. All computing information models suffer from a semantic schizophrenia. On the one hand, the model represents the domain; on

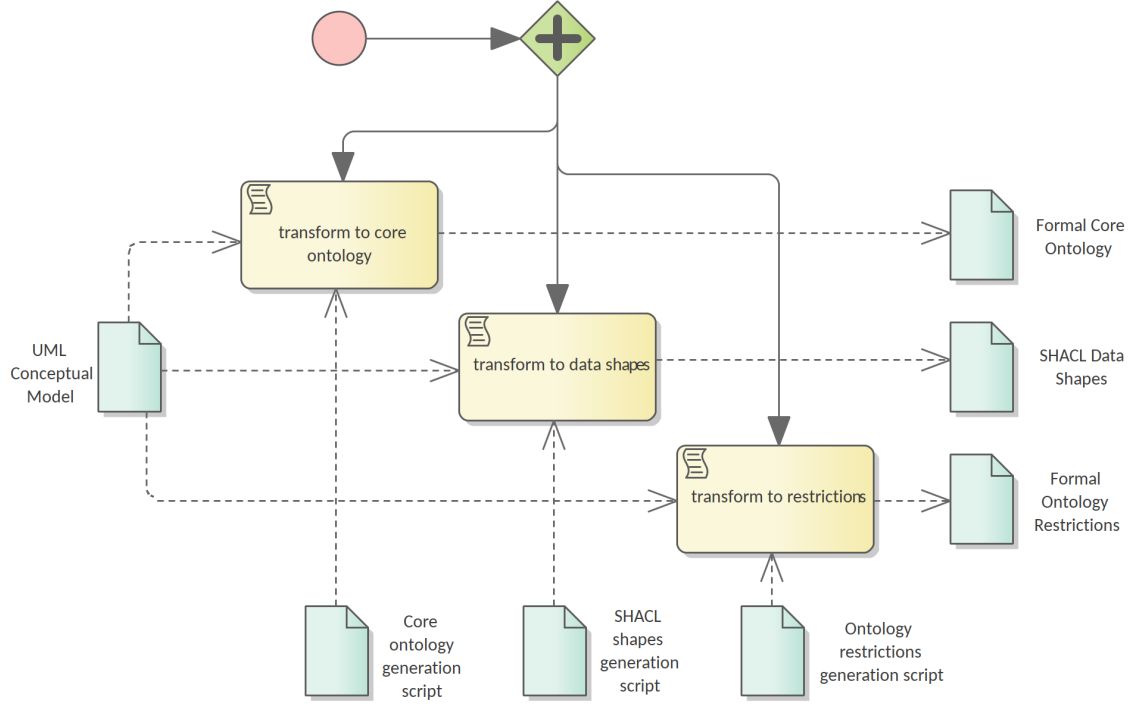

Figure 4: Generation of the formal ontology from the UML conceptual model

the other hand, it represents the implemented system, which then represents the domain. These different representation requirements place different demands upon its structure [37].

One of the common ways to manage this problem is a separation of concerns. OMG's Model Driven Architecture (MDA) [45] is a well documented structure where a model is built for each concern and this is transformed into a different model for a different concern.

Transformation deals with producing different models, viewpoints, or artefacts from a model based on a transformation pattern. In general, transformation can be used to produce one representation from another, or to cross levels of abstraction or architectural layers [44].

The process described in Section 3 adopted some of these principle and employs model transformation to achieve the project objectives.

Figure 5: XML to RDF data transformation

4.2 Layers and components

This architecture is organised in *horizontal layers* and vertically slicing *components*. The *components* reflect the organisation of the formal ontology based on a logical content division of the UML conceptual model into packages and modules. This division increases the maintainability of entire content. The models and their components are not disconnected from one another. The relations between them are represented in Figure 6 where each component is represented as an UML package. The conceptual model serves as the single source of truth, from which the three components of the formal model are derived. Each of these components can be further divided into modules.

The main ontology packages are: the *core ontology*, *data shapes*, and *formal ontology restrictions*. These formal modules are derived from the conceptual model through model transformations as described in Section 3 following the rules laid out in Costetchi [12].

The *core ontology* is the foundational, and serves as a backbone for the other components. It establishes the identifiers and the basic definitions of classes and properties.

The *data shapes* represent constraints on how the core ontology can be instantiated and the set of controlled value lists associated to it.

The *formal ontology restrictions* cover intensional class and property definitions used for deriving additional knowledge from factual information. Both, the data shapes and the ontology restrictions are defined as extensions that are flashing out the core ontology which plays, in this case the role of a backbone.

This architecture distinguishes the following layers: the *conceptual layer*, *core definition layer*, *validation layer* and *reasoning layer*. These *layers* can be thought of as formal languages with well defined boundaries and extents. The diagram in Figure 7 presents the organisation the ontology layers along two axes: *expressivity* and *detail*.

The *expressivity* of a language is the breadth of ideas that can be represented and communicated in that language. The more expressive a language is, the greater the variety and quantity of ideas it can be used to represent. The design of a language and its formalism involves an inevitable trade-off between the expressive power and its “analyzability”, which translates directly into computation difficulty. The more a formalism can express, the harder it becomes to understand, i.e. compute, what do instances of it mean.

Figure 6: The main components of the eProcurement ontology and their relation to each other and the UML conceptual model

The *detail* refers to how much description and aspects of the domain concepts are considered. This dimension plays a pragmatic rather than formal role. The rationale is that lower level of detail is useful and re-usable to a wider public, but for a set of relatively simple tasks. As the level of detail increases, the difficulty to operate on it also increases thus the user base shrinks and the task complexity rises.

The detail axis starts, on one side, from establishing the concepts identity, labels, natural language definitions; continues through establishing relations and constraints; and ends, on the other side, with formulating special logical conditions, implications and inference rules.

The *conceptual layer* accommodates informal representation of the business objects, places, things, actors in the “real world” not representations of these things in the information system. It is situated at the base of the diagram with lowest expressivity because it has not formal semantics but with a wide coverage of detail. The dotted line delimits the border between formal and informal layers.

In the conceptual layer is situated the *UML conceptual model*, which is described in Section 4.3. This model is also called *computation independent model* because it is informal and its main purpose is to interface the domain experts with an explicit conceptual representation of the domain.

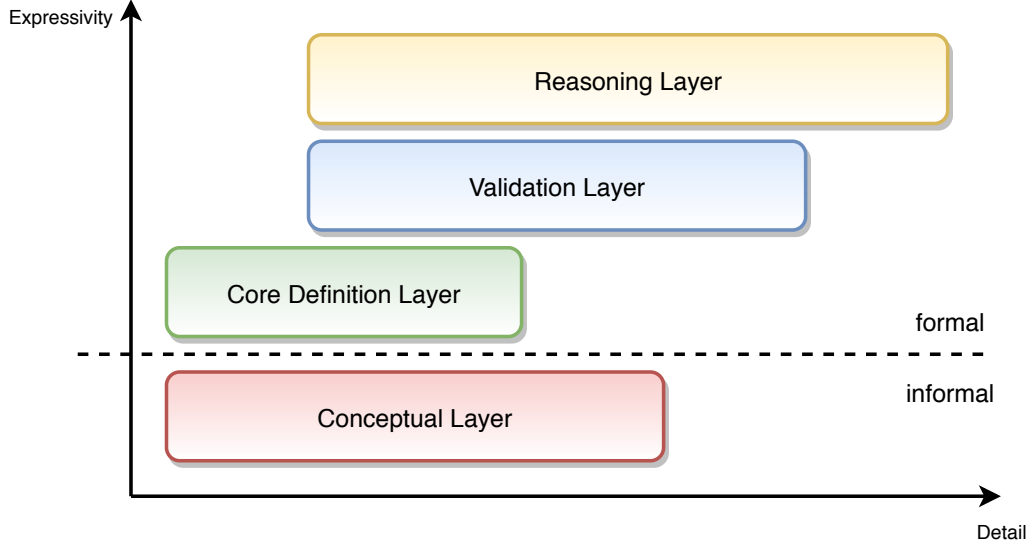

Figure 7: Expressivity and extent of the eProcurement ontology layers

In the formal section of the diagram, the expert knowledge is expressed using descriptive languages with a formal semantics (see Section 5.2), which in this architecture are primarily OWL 2[36] and SHACL[30].

The *core layer*, is situated the core ontology, which has as a primary goal to define the main concepts and relations of the ontology. It is limited to the declarative axioms of the ontology and therefore serves primarily for vocabulary and identity establishment. For this reason it is represented as having the lowest formal expressivity and the lightest level of detail in comparison to other layers. It plays the role of a backbone which is flashed out by other layers.

The *validation layer* accommodates declarations of data shapes which represent constraints on the instance data, i.e. the ABox (see Section 5.1). The assertions in this layer are interpreted done under the closed world assumption, making it possible to support validation functionality. The SHACL shapes are situated in this layer and are addressed in detail in Section 4.4.

The validation layer is situated immediately above the core definitions, being more expressive but also extending it with additional detail. Therefore it is shifted, on the detail axis, to the right towards more detail and leaving out the simple axioms as they are already covered in the core later.

The *reasoning layer* accommodates formal intensional definitions of the classes and properties. It is mostly formed of subclass restrictions and complex class definitions, and as well, domain and range specifications for properties. This layer provides assertions necessary to support reasoning functionalities for eProcurement ontology. The formal ontology restrictions component is situated in this layer and is described in Section 4.5.

Just like in the case of restrictions layer, the reasoning layer extends the core layer with higher level of detail and comprising assertions with higher expressive power. Therefore the simple details rest in the core layer permitting this one to focus on other ones. For this reason it is depicted as shifted towards the right side of detail axis.

4.3 UML conceptual model

The conceptual model is represented in UML [7] serves as the single source of truth. Thus the scope of this architecture is limited by what can be expressed in UML and how that information is utilised to generate formal statements. Each of the above functions will lead to different interpretations of the same UML model.

The primary application of UML [26] for ontology design is in the specification of class diagrams for object-oriented software. However, UML does not have a clearly specified declarative semantics, so that it is not possible to determine whether an ontology is consistent, or to determine the correctness of an implementation of the ontology. Semantic integration in such cases becomes a subjective exercise, validated only by the opinions of the human designers involved in the integration effort [28].

On the other hand, UML is closer than more logic-oriented approaches to the programming languages in which enterprise applications are implemented. For this reason in the current project we have decided to develop agreements on the informal semantics of the UML-based conceptual model. It consists of a set of explicit conventions for naming UML elements [11] and for transforming UML to OWL [12].

4.4 SHACL shapes

Application profiles represent a set of constraints on the logical model tying it to a particular system implementation. The application profiles, in this project, must be expressed using SHACL language [ref shacl spec]. The application profiles are

extending the (core) formal model and can be derived from the conceptual model through transformation, or can be designed directly in the formal representation.

4.5 Formal ontology restrictions

5 Formal considerations

5.1 Model and data relationship

DL ontologies are structured into two sets: *ABox* and *TBox*. The *ABox* consists of all (class or property) instance assertions. The *TBox* consists of all terminological axioms, i.e., of all subclass inclusion axioms. The ABox provides information about concrete individuals while the TBox describes general rules that hold for all individuals. In consequence, ABoxes tend to be much larger than TBoxes [31]. In Figure 8 is depicted the delimitation and relations between the TBox and box ABox components of the eProcurement ontology.

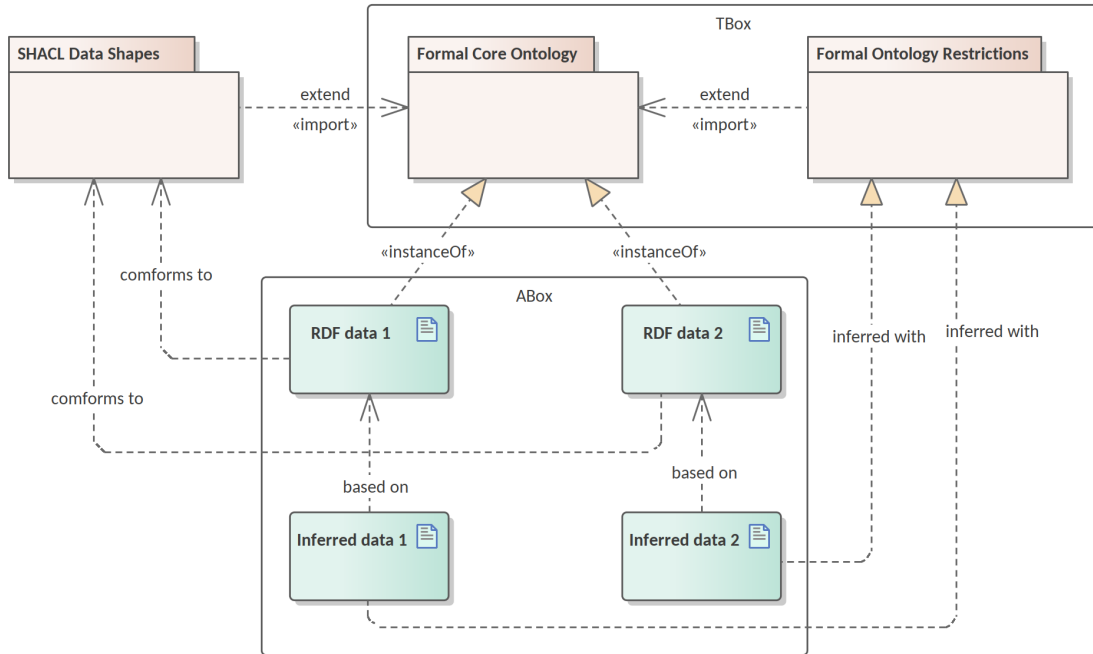

Figure 8: The relationship between the data and each of the ontology components

To explain the relevance of each component, in Figure 8, two arbitrary datasets are brought as examples. They instantiate the core ontology, which means that they comprise of factual statements of concrete entities of eProcurement classes. In order to ensure that the instance data follow minimally the intended ontology design they need to comply with a set of data shapes. Once this condition is satisfied, then, new knowledge can be inferred from the provided facts, given the domain inference rules. The new knowledge is mainly oriented to solve the classification task and does not cover other types of inference.

It is important to note that the data shapes fall out of the TBox as they serve the validation function and are based on a different set of assumptions. First they are interpreted under the closed world assumption, like in XML or RDBM contexts (see Section 5.3). Second they follow a RDF graph based semantics 5.2.

5.2 Semantics

Users of OWL [36] can actually select between two slightly different semantics: *direct semantics* that corresponds to the Description Logics (DL) [4], and *RDF-based semantics* that is based on translation of the OWL axioms into directed graphs. In this document we assume by default the direct semantics. In particular cases (i.e. SPARQL entailments and SHACL data shapes) RDF-based semantics is adopted and is explicitly mentioned in the document.

Description logics provide a concise language for OWL axioms and expressions. DLs are characterised by their expressive features. The description logic that supports all class expressions with $>$, \perp , \sqcap , \sqcup , \neg , \exists and \forall is known as \mathcal{ALC} (which originally used to be an abbreviation for Attribute Language with Complement). For a formal introduction into DL please consult Baader et al. [4].

Inverse properties are not supported by \mathcal{ALC} , and the DL we have introduced above is actually called \mathcal{ALCI} (for \mathcal{ALC} with inverses) [31]. Many description logics can be defined by simply listing their supported features. We will use this notation when discussing degrees of expressivity for the ontology layers in Section 5.5.

Computing all interesting logical conclusions of an OWL ontology can be a challenging problem, and reasoning is typically multi-exponential or even undecidable. To address this problem, the recent update OWL 2 of the W3C standard [39, 36] introduced three profiles: *OWL EL*, *OWL RL*, and *OWL QL*. These lightweight sublanguages of OWL restrict the available modelling features in order to simplify

reasoning. This has led to large improvements in performance and scalability, which has made the OWL 2 profiles very attractive for practitioners [31].

On the other hand, the validation data shapes are expressed using Shapes Constraint Language (SHACL) [30]. Its semantics is based on RDF graphs but full RDFS inferencing is not required. SHACL processors may operate on RDF graphs that include RDF entailments [38] and SPARQL specific entailments [35]. The entailment regime specifies conditions that address the fourth condition on extensions of basic graph pattern matching [29, 38].

This architecture delimits different concerns in Section 4.2 in a stack of layers and assigns levels of expressivity to each of the layers in Section 5.5.

5.3 Open and closed world assumptions

In the formal systems of logic used for knowledge representation, reasoning is the process through which logical conclusions are derived from a set of premise known to be true or assumed to be true by the laws of valid inference (inference rules).

In the eProcurement ontology checking consistency and deriving new knowledge is foreseen as a valuable functionality beyond the knowledge representation and interoperability establishment.

Inferencing is impacted by what is assumed about the knowledge base. The important assumptions to consider are: (a) whether the knowledge base is considered complete – the closed-world assumption (CWA); or (b) whether the knowledge base (proper knowledge base) is in a state of continuous progression – the open-world assumption (OWA) [14].

Under the *closed-world assumption* it is presumed that a statement that is true is also known to be true. Therefore, conversely, what is not currently known to be true, is false [42]. The opposite of the closed-world assumption is the *open-world assumption* stating that lack of knowledge does not imply falsity. The truth value of a statement may be true irrespective of whether or not it is known to be true.

The eProcurement data is fragmented across information systems. It represents concerns specific to different steps in the procurement process. Performing local reasoning with such incomplete knowledge is therefore necessary functionality for the eProcurement project.

Semantic Web languages, including OWL, make the open-world assumption. The absence of a particular statement within the web means, in principle, that the statement has not been made explicitly yet, irrespective of whether it would be true or not, and irrespective of whether we believe that it would be true or not. This stance is also very convenient for decentralised knowledge bases over the internet, where information may be accessible, outdated, contradictory, inaccessible or missing[14].

For validation purpose, in particular, a closed world assumption needs to be made. This concerns the data shapes expressed in SHACL language. In these case, the knowledge base must be considered complete in order to assess whether it fulfils the imposed constraints or recommended shapes. So everything that is not known to be true must be considered as false.

The eProcurement data must be validated within its local context. The data must be conformant to the information needs and aspects specific to the procurement phase and, possibly, to the information system that handles it. It is, therefore, foreseeable that multiple validation schemes and application profiles have to be developed specific to different phases and aspects of the procurement process. These schemes must extend and flesh out the core ontology, which is the ontology backbone, with levels of specificity and detail as necessary.

5.4 Conformance

The eProcurement ontology should be expressed in OWL 2 language and in conformance with the conditions listed in Krötzsch et al. [32].

SHACL conformance

RDF conformance for the data

UML conformance for CM

5.5 Expressivity levels

In the layered approach described in [ref architecture section], different expressivity levels are necessary for each layer. In this section we briefly describe these levels of expressivity and relate them to OWL sublanguages [15] and profiles [34].

Model/Component	Language
Conceptual model	UML (informal)
Core ontology	OWL Lite
Data shapes	SHACL (SPARQL 1.1 entailment)
Ontology restrictions - simplified	OWL QL, OWL EL, OWL RL
Ontology restrictions - complete	OWL 2
Special inference rules (out of scope)	SWRL

Table 1: The components and the corresponding language dialect

6 URI policy

The report on high value datasets from EU institutions [3] mentions eProcurement data as being of special importance and high value. It also provides guidelines and recommendations for publishing government data approached both from the publisher’s point of view, and the reuser’s point of view.

eProcurement ontology must be published in multiple formats, including RDF. This entails the assignment of identifiers to each term and, to be useful in the kind of linked data applications envisaged, those identifiers should be HTTP URIs and commit long term URI persistence.

6.1 General considerations and recommendations

There is a five start rating [6] to measure published data reusability using a five start rating. This rating system is based on four design principles proposed in Berners-Lee [5], to which eProcurement ontology subscribes.

- Use Uniform Resource Identifiers (URIs) to uniquely identify things (data entities);
- Use HTTP URLs, corresponding to these URIs, so that information can be retrieved;
- Provide metadata using open standards such as RDF;
- Include links to related URIs, so that people can discover more things.

Moreover the eProcurement URI scheme must subscribe to the “Cool URIs” recom-

mendations [13] and ensure that they don't change [9].

- *Simplicity.* Short, mnemonic URIs will not break as easily when sent in emails and are in general easier to remember.
- *Stability.* Once you set up a URI to identify a certain resource, it should remain this way as long as possible.
- *Manageability.* Issue your URIs in a way that you can manage. [13]

The ISA² study on persistent URIs [2] provides a set of design and management principles. They are completed by a more recent study on URI design patterns [16], in the context of promoting semantic interoperability, identified good design practices for the local part of URIs under the `http://data.europa.eu` domain (see Section 6.2).

- *Use a template.* Pre-defined approach to URI design, using for example URI templates, can help organisations follow a logical structure [2, 16].
- *Avoid stating ownership.* The URI template above does not include the name of the organisation or project that minted the URI [2, 16].
- *Avoid version numbers.* URIs should remain stable between versions and new ones minted for new terms [2, 16].
- *Re-use existing identifiers.* Where resources are already uniquely identified, those identifiers should be incorporated into the URI [2].
- *Avoid using auto-increment.* Minting new URIs for large datasets will need to be automated and the process must be guaranteed to produce unique identifiers, but not sequentially allocated [2].
- *Avoid query strings.* Query strings (e.g. `?param=value`) are usually used in URLs as keys to look up terms in a database. But these constructs should not be used in the URIs but left for particular implement [2].
- *Avoid using file extensions.* For similar reasons as above [2].
- *Mix meaningful and opaque strings.* Meaningful URIs should be avoided in the URI segments which carry a risk of renaming (see Section 6.2) for any foreseeable reason [16].
- *Employ URI sub-divisions.* When necessary, create subdivisions in the URI

pattern following a logical patterns and keeping the namespace maintainable. However this practice must be kept to minimum if at all employed [16].

6.2 Persistence

In 2014, the ISA Programme supported an informal Task Force working on a common policy for the management of persistent, HTTP-based URIs of EU institutions comparable to the virtues of DOI identification scheme [17]. A Persistent URI Service on the `http://data.europa.eu` sub-domain was established that is responsible for the registration and management of persistent URI namespaces and the forwarding of HTTP requests (URI redirection) towards the Publications Office local register for the eProcurement ontology (see Section 6.3).

`http://data.europa.eu/{collection-id}/{local-register-space}`

Publications Office was allocated the following persistent URI namespaces for usage in the context of eProcurement ontology. Section 6.3 provides the specifications on the URI structure and the local part organisation.

- `http://data.europa.eu/abc`
- `http://data.europa.eu/def`

Regarding URI design, the main consideration of creators should be that when a URI is created, all its parts should be resistant to change. For instance, locations and organisation names can change, and therefore should not be used in URIs. First and foremost, when introducing semantics in URIs, the strings used need to reflect what the resources are (i.e. intrinsic characteristics such as the type or nature), not who owns them or where they are [16].

When creating a URI, its owner can never be certain of who will be using it and can therefore not notify every concerned individual of future changes. It is therefore paramount that URIs are designed carefully with the specific goal of making them persistent, in theory forever [9]. Persistence is a vital component of URI design. Since the local part of a URI is under the control of the institution that owns it (in this case Publications Office), it is up to the owners to ensure that the way they design local IDs enables the persistence of the URI as a whole.

It is recommended to identify all eProcurement resources with URIs which have opaque local identifiers. However, in the case of TBox resources, such as the ontology and the data shapes, mnemonic local segments may be used.

6.3 URI scheme

The URIs are best maintained using a pre-defined set of patterns and templates.

Ontology reference : to be used in the ontology header as reference to the ontology.

`{baseVoc}/ontology/{ontologyName}`

Ontology reference : to be used in the ontology header to refer to the current RDF document.

`{baseVoc}/ontology/{ontologyName}#{documentRef}`

Ontology resources : to be used to refer to resources defined within the ontology, such as classes, properties and special individuals.

`{baseVoc}/ontology/{ontologyName}#{resourceName}`
